Cryptosporidium

Q: What is cryptosporidiosis?
Cryptosporidiosis is a diarrheal disease caused by microscopic parasites of the genus Cryptosporidium. Once an animal or person is infected, the parasite lives in the intestine and passes in the stool. The parasite is protected by an outer shell that allows it to survive outside the body for long periods of time and makes it very resistant to chlorine-based disinfectants. Both the disease and the parasite are commonly known as “Crypto.”

During the past two decades, Crypto has become recognized as the leading cause of waterborne disease among humans in the United States. The parasite may be found in every region of the United States, and throughout the world, in drinking water and recreational water (for example, swimming pools, hot tubs, jacuzzis, fountains, lakes, rivers, springs, ponds or streams).

Q: Where is Cryptosporidium found?
Cryptosporidium lives in the intestines of infected humans or animals. Millions of Crypto parasites can be released in a bowel movement from an infected human or animal; consequently, it is found in soil, food, water, or surfaces that have been contaminated with infected human or animal feces.

Q: How is cryptosporidiosis spread?
While you cannot become infected with Crypto through contact with blood, the parasite can be spread in a number of ways.

- Putting something into your mouth or swallowing something that has contacted the feces of a person or animal infected with Cryptosporidium.
- Swallowing recreational water contaminated with Cryptosporidium from sewage or feces of humans or animals. Cryptosporidium can survive for days in swimming pools with adequate chlorine levels.
- Eating uncooked food contaminated with Cryptosporidium. Thoroughly wash all vegetables and fruits you plan to eat raw with clean, safe water.
- Accidentally swallowing Cryptosporidium picked up on hands from surfaces contaminated with feces from an infected person (for example, bathroom fixtures, changing tables, diaper pails or toys).
**Q: What are the symptoms of cryptosporidiosis?**

The most common symptom of cryptosporidiosis is watery diarrhea. Other symptoms include dehydration, weight loss, stomach cramps or pain, fever, nausea or vomiting. Symptoms usually last 1 to 2 weeks in people with healthy immune systems, but can last more than 4 weeks. Some people with Crypto will have no symptoms at all. While the small intestine is the site most commonly affected, Cryptosporidium infections could possibly affect other areas of the digestive or respiratory tracts.

**Q: Who is most at risk for contracting cryptosporidiosis?**

People who are most likely to become infected with Cryptosporidium include:

- those involved in day care centers (diaper-aged children, child care workers, parents of infected children, etc);
- outdoorsmen who drink unfiltered, untreated water (backpackers, hikers, campers, etc.);
- swimmers who may swallow water while swimming in pools, lakes, rivers, ponds and streams;
- people who drink from shallow, unprotected wells; and
- people who swallow water from contaminated sources.

Contaminated water includes water that has not been boiled or filtered. Several community-wide outbreaks of cryptosporidiosis have been linked to drinking municipal water or recreational water contaminated with Cryptosporidium.

**Q: Who is most at risk for getting seriously ill with cryptosporidiosis?**

Although Crypto can infect all people, some groups are more likely to develop more serious illness.

Young children and pregnant women may be more susceptible to the dehydration resulting from diarrhea and should drink plenty of fluids while ill.

People with severely weakened immune systems are at risk for more serious disease, as symptoms may be severe and could lead to serious or life-threatening illness. Examples of persons with weakened immune systems include those with HIV/AIDS, cancer and transplant patients who are taking certain immunosuppressive drugs, and those with inherited diseases affecting the immune system.

**Q: Have Cryptosporidium parasites been found in Oklahoma public water supplies?**

DEQ requires all public water supply systems using surface water as a source to filter the water before distributing it to the public. A properly designed and operated filtration plant can remove a high percentage of Cryptosporidium organisms. Because of this requirement, the risk of cryptosporidiosis is probably smaller in Oklahoma than in other parts of the US where filtration is not practiced.

Most public water supply wells are likely not susceptible to Cryptosporidium contamination; however, springs and shallow wells can be susceptible if the water that they yield has not been filtered underground. DEQ has evaluated public water supplies using springs or shallow wells to determine if they are subject to contamination from surface water. Those that were found to be surface water impacted are no longer being used or are now being filtered.
Q: How can I get my water tested for crypto?
Contact DEQ’s State Environmental Laboratory at (405) 702-1000 or (866) 412-3057, or by emailing selsd@deq.ok.gov to schedule a sampling event.

Q: Where can I get more information about crypto?
The Web site for the Center for Disease Control (CDC) has a very good Fact Sheet on Cryptosporidium and cryptosporidiosis. Information from the CDC has been used for this Fact Sheet and more information may be found on CDC’s Web site.
